In developing countries, owners of private vehicles tend to depend on their own modes and the modal shift couldn't be expected without effective modal-shift measures based on the trip characteristics and issues in the city.

This study aims to analyze the results of Person-Trip surveys conducted in the Asian Megacities focusing on private vehicle dependence and trip length, to understand the mobility's characteristics and problems / challenging in Asian Megacities. The study results are expected to lead to suggestion on effective modal shift measures.

The trip rate (number of trips per person per day) by representative mode and modal share by trip length were examined and differences between car owners and non-car owners are observed. Some cities such as Dhaka and Colombo show significant difference on the trip rate between car owners and non-car owners, and high modal share for walkable distance trip of car owners. These findings suggest that car owners strongly depend on the private cars for there daily trips.

Key Words : Person Trip Survey, Trip Length, Private Vehicle Dependence, Asian Megacities

1. INTRODUCTION

(1) Background

Generally, owners of private vehicles tend to depend on their own modes and don't include other modes as chaices for their trips. This trend is more prominent in the developing countries, where the service level of public transport is poor. With the economic growth and motorization, the modal share of the private vehicles has been increased rapidly, inducing serious problems for environment, the quality of urban life and the accessibility of various acctivities.

In megacities of developing coutries, transport projects such as urban rail development are on-going,to ensure public mobility, contribute to effective land use development by building a transport backbone, promote the growth of its influence areas. However, the strong dependency on the private modes would inhibit the expected modal shift and make such transport projects ineffective. To achieve succefful modal – shift, measures based on the trip characteristics and issues in the city must be implemented.

(2) Objectives

This study examines the person trip survey results conducted in Megacities in Asian Developping Countries, focusing on private vehicle dependence. The modal share by household vehicle ownership group are copared to understand the characteristics by case study cities, and modal share for intra-zonal trip (short distance trip) are reviewed as an indicator of private vehicle dependence. For the cities that car-dependent traffic behaviors are observed, these behaviors are analyzed to surmise there motives. The results are expected to be discussed on effective modal shft measures

2. CASE STUDY CITIES

The case study cities are selected according to the following criteria:

- Cities where comprehensive Person Trip Survey (PT Survey) was conducted by apan International Cooperation Agency (JICA) recently: For such survey, the sample rate was conventionally about 2.0 % of total households, has been limited to about 1.0 % due to the budget constraint. However, calibration by several supplemental traffic surveys assures the precision in sampling and this paper urilizes the PT survey results ¹⁾.
- Cites with various progress of motorization : The results by vehicle ownership rate are compared and relationship with the private vehicle dependency is examined.
 - Cities with and without Urban Railway: urban railway provides significant impact on urban transport characteristics must be compared, to discuss implication on the development of urban railway, which development projects are on-going in many Asian cities.

Based on the aboved, five cities shown in Table 1 were selected as the case study cities.

3. URBAN TRANSPORT CHARACTER-ISTICS OF CASE STUDY CITIES

(1) Metro Manila, Philippines⁴⁾

a) City Profile

As the capital region of the Philipinnes, the population growth and suburbnization have been pro-

 Table 1
 Profile of Profiles of Case Study Cities

gressed and the substantive metropolitan area has 22 million of population.

While the expansion of the urban area has been progressed rapidly, development of transport infrastructure as the countermeasures are slow and there is huge demand-supply gap. People in middle - income group who live in suburban are forced to spend long commute time due to the traffic congestion. Urban development associated with the economic growth is active and high-rised buildings have been constructed without appropreate urban plan, creating high – population density area.

For the characteristics in urban transport fields, Metro Manila has experienced both of rapid motorization and urban railway development at the same time. And there are various road – based public transport, such as bus, jeepeney (minibus originally made from U.S. military jeep), tricycle (motorcycle taxi with sidecar), pedicab (bicycle taxi), FX taxi (passenger service by Utility Vehicles), and P2P (premium direct bus service connecting the suburbs to the central business districts).

b) Person Trip Survey and Modal Share

In Metro Manila, Person Trip Survey had been conducted several times and the latest one was conducted by "The Project for Capacity Development on Transportation Planning and Database Management in the Republic of the Philippines (MUCEP)" in 2014 ⁵⁾. Table 2 shows the modal share by Household Car Ownership in 2014. Comparing the members in car own households and non-car own households, there is difference in the share of walking trips (car own households: 14.0 %, non- car own households: 33.5 %,).

Table 2Modal Share in Metro Manila, by Household Car
Ownership (2014) 5)

(2) Ho Chi Minh City, Vietnam

a) City Profile 4)

Vietnamese Cities show very high ownership rate of motorcycleis. The Vietnamese traditional residential blocks consist of middle rised housings (3-5 storeys) and narrow street (2 - 3 m of width) and accessility is provided only for motorcyclists and door-to-door movements are ensured by on-street parking. These environment enhanses the usage of motorcycle in the daily life. Although these trend has been increasingly significant in recent years, the number of private cars also has been increased.

b) Person Trip Survey and Modal Share

In Ho Chi Minh City, Person Trip Survey was conducted in two times by JICA, "The Study on Urban Transport Master Plan and Feasibility Study in Ho Chi Minh Metropolitan Area (HOUTRANS)" in 2002¹³⁾ and "Data Collection Survey on Railways in Major Cities in Vietnam (METROS)" in 2013⁶⁾.

According to the Person Trip Survey in 2013, the household motorcycle ownership ratio was more than 90 %. In this paper, the modal share by personal availability of motorcycle and car was compared as shown in Table 3. Even for non-vehicle available group, modal share of motorcycle is nearly half of total trips and the most of them are picked up and dropped off by others. The number of samples in car available group is limited but more than 40 % of there trips are made by private cars.

(3) Yangon, Myanmar

a) City Profile 4)

Yangon, the former capital of Myanmar with a population of 5.2 million (as of the 2014 census), is the country's largest commercial hub. The population growth and urbanization have been progressed rapidly. Although the population density of the whole city is not high, there is downtown area which was developed in the colonial era and low-density area being expanded in suburbs. Myanmar shifted to democrasization from long miniltary administration and has been exposed to the waves of internationalization, and Yangon has experienced rapid urbanization and motorization.

Bus transport plays major role of urban transport and carry about 2 million pasengers a day. It is partly due to the restriction of motorcycle use in urban area. Considering the importance of bus service, the Government has committed to reform the system drastically but further improvement is required in many fields.

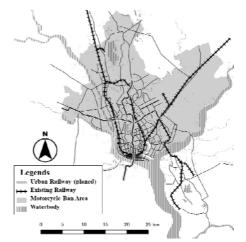

Figure 1 Transport Map in Yangon City ¹⁴⁾

b) Person Trip Survey and Modal Share

As a part of the Project for Comprehensive Urban Transport Plan of Greater Yangon (YUTRA, 2013⁷⁾), Person Trip Survey was conducted. Table 4 shows the modal share by Household Car Ownership. The share of walking trip for members in car own households is higher than other cities.

| | | Car C Housel | | Non-Car Own HouseHolds | | Tot | al |

Table 4Modal Share in Yangon Area, by Household CarOwnership (2014)

(4) Dhaka, Bangladesh

a) City Profile⁹⁾

Dhaka City is the capital of the People's Republic of Bangladesh. The Metropolitan Area called RAJUK, as the name of the Capital Development Authority, has 14.8 million residents in 1,500 km² of its area. With the very high population density, various urban problems including serious traffic congestion can be observed. Due to the rapid motorization, difficulty of land acquisition, and financial and institutional matters, the traffic problems seem to be difficult to solve.

b) Person Trip Survey and Modal Share

Household Interview Survey were conducted by "Preparatory Survey Report on Dhaka Urban Transport Network Development Study in Bangladesh (DHUTS)" in 2009⁸⁾ and "The Project on the Revision and Updating of the Strategic Transport Plan for Dhaka(RSTP)" in 2014⁹⁾. Both Studies were founded by JICA, and the former collected only the city area and latter was conducted to supplement to collect samples in suburban Area.

Table 5 shows the modal share by household car ownership. For the members of Car Own Households, the share of private mode is high and walking trip is much lower than non-car own households group. And rickshaw (bicycle - taxi) has a significant role in mobility for the citizens in both groups.

(5) Colombo, Sri-Lanka

a) City Profile¹⁰⁾

Colombo Metropolitan Area is the largest metropolitan area in Democratic Socialist Republic of Sri Lanka. The population was 3. 7 million inhabitants in 2012.

Current traffic congestion becomes serious during the morning and evening peak periods in the city centre and the surroundings.

Less utilization of high occupancy vehicles, a lack of facilities for pedestrians and bus passengers, an insufficient capacity of public transport and poor enforcement of traffic rules aggravate the situation.

b) Person Trip Survey and Modal Share

Under "The Urban Transport System Development Project for Colombo Metropolitan Region and Suburbs (CoMTrans)^{"10}, Home Visit Survey was conducted to collects the latest travel activity information of the residents along with the socio- economic information in 2013. Table 6 shows the modal share by household car ownership. The members of Car Own Households tend to rely on the private mode and the share of walking trip is just 4.7% much lower than non-car own households group, 19.9%. For non car own households members, the share of motorcycle is high, reflecting the high ownership of motorcycles.

Table 6Modal Share in Colombo, by Household CarOwnership (2013) 9)

(6) Comparison of Trip Rate by Travel Mode

Figure 2 visualizes the trip rate (the number of trips per population aged 5 or over) by household car ownership in Case Study Cities. Contribusion by representative travel mode is also illustrated. Generally, the trip rates for members in car own households are higher than non-car own households members. On the other hand, the walking trip rate is much lower in car own households members.

The difference on the walking trip rate by car ownership varies by city. Among the case study cities, Dhaka and Colombo show especially significant difference. It implies that car owners in the cities strongly depende on the private cars and use there private mode for very short distance.

In Yangon, the difference in the walking trip rate by car ownership group is small. The registered vehicles per population is still low and car-dependent lifestyle may not be established among people yet.

4. ANALYSIS ON MODAL SHARE BY TRIP LENGTH

(1)Methodology

As the viewpoint of analysis on the mode choice characteristics, modal share by trip length was focused on. If the share of private vehicles are high even in short trip length, the prople in the city might depend on there private modes. To estimate the trip length by Origin - Destination (OD) pair, the transport network file (format: JICA STRADA) was utilized. And it must be noted that the mode choice characteristics markedly different by the location. For example, urban facilities are concentrated in city centre and people can access the destination by walk. On the other hand, facilities are dispersed in suburban area and the share of walking trips is tend to be small. Additionally, traffic analysis zones of the Person Trip Survey are larger in Suburban Area and it is difficlut to identify the intra-zonal trip is walkable distance or not. In this paper, only OD pairs within the defined urban cores are picked up. The network, picked up urban cores, and selected traffic analysis zones are summarized in Table 7. For the picked-up urban cores, the average land area of the traffic analysis zones ranges from 100 ha (Yangon) to 250 ha (Dhaka). Most of the intra-zonal trips can be assumed as walkable distance.

Table 7 Profile of Profiles of Case Study Cities

| | | | Total | | Picko Urbai | ed-up 1 Area |
|------------------------------------|---------|------------------------|-------|---------------|----------------|----------------------------|
| City Name | Network | TAZ and Picked Up Area | No | Area (km²) | No | Area (km ²) |
| Metro Manila (Philipiness) | | | 350 | 3,953 | 161 | 197 |
| Ho Chi Minh City (Vi- etnam) | | | 275 | 6,445 | 133 | 199 |
| Yangon (Myanmar) | | 0 20 40 60 100 km | 389 | 1,529 | 149 | 156 |
| Dhaka (Bangladesh) | | 0 20 40 60 80 100 km | 144 | 1,554 | 87 | 216 |
| Colombo (Sri-Lanka) | | | 462 | 3,745 | 138 | 194 |

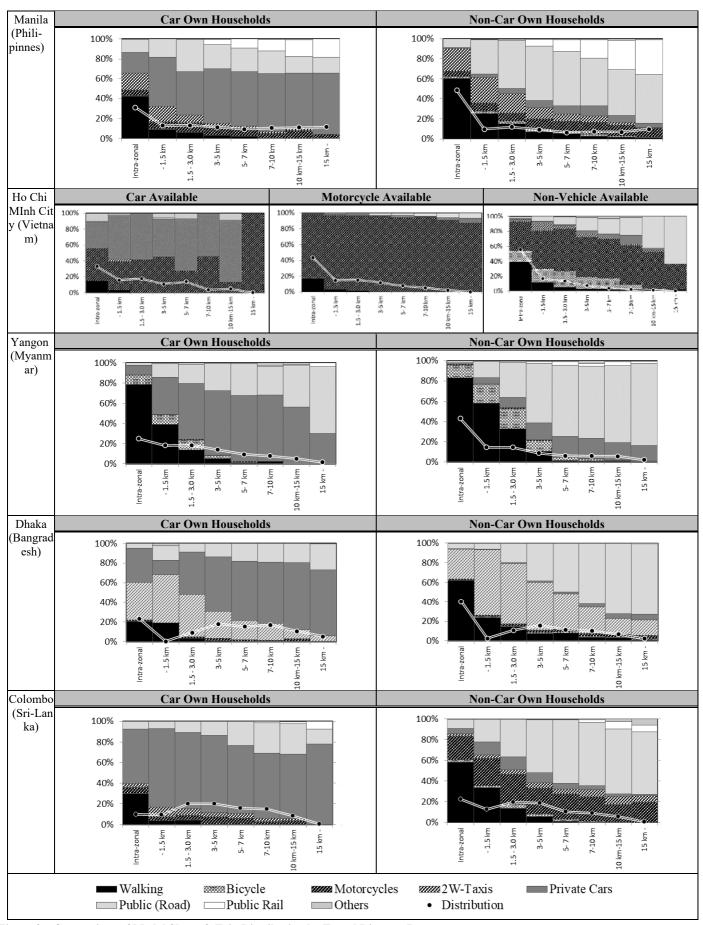

Figure 3 Comparison of Modal Share & Trip Distribution by Travel Distance Range

(2)Findings

The results are illustrated in Figure 3. The line glaph shows the distribution of total number of trips by trip length.

Except for Colombo, the inter-zonal (very short distance) trips shows the highest propotion among the trips within the picked up urban core. And the share of walking is more than 60 % for non-car own household group in the most case study cities.

The modal share of intra-zonal trips for car own household group, can be considered as the important indicator of the car dependence in the case study cities. In Metro Manila and Yangon, walking trips account for large portion. On the other hand, car owners in Dhaka and Colombo shows very low modal share of walking trips. The result in Ho Chi Minh City shows isolated charactiristics. Even members in non-vehicle available group rely on motorcycles and the share of walking trips is just 40 % in intra-zonal trips.

Not only the trip rate by walking, there is difference on the modal split for intra-zonal trips between car own household group and non-car own household group. As the factors of the results, following can be assumed:

- Walkability of the street
- Availability of private vehicles (number of registered vehicles)
- · Availability of parking space and parking fee
- Perception on security and safety during walking trip

The relationship of these factors and the car dependent travel behavior would be investigated.

5. CONCLUSION AND NEXT STEPS

In this study, trip rate by representative travel mode and modal share by travel distance in the case study cities were examined and the differences on share of walking trips between private vehicle owners and non-owners were observed. For the cities with especially significant difference, it can be pointed out that the car owners might depend on private vehicles strongly, without reasonable judgement for mode choice.

For further studies, the relationship of these factors and the car dependent travel behavior would be investigated. And the background of the car-dependent traffic behaviors must be verified to discuss on effective modal shft measures. .
