1. INTRODUCTION

Since the amount of groundwater abstraction has been rapidly and continuously increasing worldwide, achieving sustainable management of groundwater resources is one of the essential objectives for the future of developing countries like Vietnam, especially when the rising demand for clean drinking water is highly considered (Mende et al., 2007). In addition, annual cycle in groundwater levels associates with those in rainfall and river water levels, but long-term trends results from increasing groundwater withdrawal (Bui et al., 2012). The Vietnamese capital, Hanoi, is the target area addressing the sustainability issue of groundwater resources because: (i) the groundwater abstraction has been rapidly and continuously increasing and the demand for clean water is becoming rather urgent; (ii) the water supply significantly depends on this valuable resources (up to almost 100%) for three main purposes such as irrigation, domestic, and industrial uses; and (iii) the rapid exploitation of the groundwater without an appropriate management system has reportedly caused a series of adverse impacts such as drying up of shallow wells, decline of groundwater level locally and seriously, and land subsidence (Bui et al., 2012; Tong, 2008). The question is that groundwater abstraction is for a better lives, but how not to make the human activities harmful to our social- environmental conditions is also essential for sustainable development (Bui et al., 2011b) of the Capital.

Therefore, taking as much as possible the advantage of the historically scientific development of the area, this paper is going to at first (i) review a number of studies regarding to the relevant issues to have better understanding about of groundwater's estimated recharge and exploitable amounts in Hanoi; secondly (ii) estimate the total amount of groundwater abstraction for three main irrigation, domestic, and industrial purposes based on The Scientific Research No.TNMT.02.33 of Ministry of Natural Resources and Environment of Vietnam; and finally (iii) value two sustainability indicators suggested by UNESCO (UNESCO, 2007) in order to provide us the general sustainability view of groundwater abstraction situation for Hanoi development.

2. STUDY AREA

Hanoi area is around 3324.5 km² and includes 30 separated districts. The population of about 7,095,900 habitants in 2014 accounts for the highest population density in Vietnam. Hanoi belongs to the tropical monsoonal area with two distinctive seasons in the year, the rainy season from May to October and the dry season from November to April of the following year. The annual rainfall is about 1,550 mm of which rainfall in the rainy season accounts for about 70-80%. The average humidity is about 80%, and the average temperature is around 24.3°C. Evaporation is quite high with an annual average of 933 mm (Tong, 2008).

Hanoi also has a dense river network and is mainly supported by Red River, one of two biggest river systems, with the basin areas of 155,000 km², approximately, and by several Red River-linked systems such as Nhue, Duong, Tolich, Cau, and Calo. There are also 111 lakes with the total surface of up to 2180 hectares and Westlake is the biggest with the area of 526 hectares, as showed in **Fig.1**. However, the rapidly economic development and fast socialization and urbanization have put pretty much pressure on the river basin environment. This surface water system is recently polluted by organic compounds, in which, the lakes especially in this study area are significantly polluted (Tong, 2008). That is the main reason why the groundwater resources have become main water supply for the local inhabitants.

3. FORMATION OF GROUNDWATER RESOURCES IN HANOI

Hanoi's groundwater resources mainly exist in the topmost Holocene unconfined aquifer (HUA) and the shallow Pleistocene confined aquifer (PCA), while cleft and karst water exists in the Neogene water bearing layer and the Mesozoic fractured zones (Bui et al., 2011a).

In HUA layer, silty clay and various kinds of sands mixed with gravels are the main components. The HUA thickness is variously distributed, more than 35 m with an average of 15 m, approximately. The transmissivity

Fig.1 Study area, Groundwater and River Network.

and the specific yield of this layer ranges from 20 to 1,788 m²/day and from 0.01 to 0.17, respectively. The HUA, thus, is distributed at a rate of about 55% in the south of the city area, and has a relatively high potential of groundwater resources, sufficient for the small to medium scale domestic water supply.

The shallow Pleistocene confined aquifer (PCA) depth is also widely distributed, less than 10m in the North of the Soc Son District, around 20m in Dong Anh District, and up to 40 m in the South of the Red River. The PCA layers have a complex components of sand mixed with cobbles and pebbles. Moreover, the PCA thickness is variously changed, with the highest value of up to 50m and the average of 35 m approximately and trend increasing from the North to the South. With a large range of transmissivity from 700 to 2,900 m²/day, and the specific storativity from 0.00004 to 0.066, PCA is the highest potential of groundwater resources and widely distributed at a rate of about 80% in the south of the city, serving the most important aquifer for the area water supply (Bui et al., 2011a).

4. RESULTS AND DISCUSSIONS

(1) Groundwater recharge in Hanoi

The term “recharge” has been defined as “as the downward flow of water reaching the water table, adding to groundwater storage” in the book of “Estimating Groundwater Recharge” (Richard, 2010). The author mentions that the definition does not include water flow to an aquifer from adjoining groundwater system such as water movement from an unconfined aquifer to an underlying aquifer. This paper, thus, considers the recharge to Hanoi groundwater resource is the same as recharge to the HUA from precipitation.

Fig.2 Recharges in 2005, 2010, and 2014.

Based on the data from national water resource monitoring and investigation projects of National Center of Water Recourses Planning and Investigation in period of (1995-2014), the recharge amounts is various from region to region with the minimum of 85 mm/year (at monitoring no.Q65 in Hoang Mai District in 2014) and the maximum of 1,028.52 mm/year (at monitoring no.Q67 in Tay Ho District in 2010). The average recharge estimation for Hanoi is about 276 mm/year (Fig.2).

Average groundwater recharge =

$$\begin{aligned}
 &= 276[\text{mm/year}] \times 10^{-6}[\text{km/mm}] \times 3324.5[\text{km}^2] \\
 &\approx 917,562 \times 10^{-6}[\text{km}^3/\text{year}] \\
 &= 917,562,000[\text{m}^3/\text{year}]
 \end{aligned}$$

(2) Exploitable groundwater resources

The term “exploitable” means the amount of water that can be annually abstracted from a given aquifer under current socio-economic constraints, political priorities and ecological conditions (UNESCO, 2007). The latest estimation is carried out by The National Center of Water Recourses Planning and Investigation in 2015. The amount of 6,199,140m³/day, combines natural dynamic storage, elastic static storage, a part of gravitational static storage, and the entrained storage, as the following formula:

$$Q_{kt} = Q_{tn} + \frac{Q_{dh}}{t} + \frac{\alpha V_{tl}}{t} + Q_{ct} \quad (1)$$

where:

Q_{kt} : the exploitable groundwater resources, m³/day

Q_{tn} : the natural dynamic storage, m³/day

V_{dh} : the elastic static storage, m³

V_{tl} : the gravitational static storage, m³

Q_{ct} : the entrained storage, m³

α : the coefficient associating with natural and gravity static storage, %

t : exploitation time, 27 years (10⁴ days) as usual.

(3) Groundwater abstraction

The amount of groundwater abstraction for different uses such as agricultural, industrial and domestic uses, have been reported by Scientific Research No.TNMT.02.33 of Ministry of Resources and Environment (NAWAPI, 2015) (Table 1).

Table 1 Hanoi Groundwater Abstractions (Sources: The Scientific Research of MONRE, No.TNMT.02.33) (NAWAPI, 2015)

Group 1. List of abstraction amounts from The Groundwater Supply Companies				Group 2. List of main groundwater abstraction locations

Abstraction by Group 3			733,016	Abstraction by Group 2		88,946	

Hanoi groundwater abstraction mainly includes (i) public exploitation wells managed by 25 Clean Water Supply Companies, (ii) private wells managed by approximately 47 schools, institutes, factories, small industries, communities, and so on, and (iii) 793,657 household wells. The sub-total groundwater abstraction estimations of group (i), (ii), and (iii) are 977,600 m³/day, 88,946 m³/day, and 733,016 m³/day, respectively.

Total groundwater abstraction is:
 = 977,600 + 88,946 + 733,016
 = 1,799,562 [m³/day]

The percentages of the abstraction with respect to the recharge and exploitable are calculated. According to the classification of the Groundwater Indicators Working Group (UNESCO, 2007), the percentage of abstraction with respect to the exploitable is falling into the first scenario of less than 90%. The percentage of 29% shows that the groundwater resource is ‘underdeveloped’ and the use could probably be further developed. The result also shows that Hanoi Capital still has a substantial potential in groundwater exploitation. There is a definite need to improve economic performance in groundwater investigation and exploitation for the Capital.

In addition, the other sustainability indicator is about 72%, less than 90%, also in the first scenario of the abstraction with respect to groundwater recharge presenting that the abstraction situation in Hanoi is generally toward sustainable development.

5. CONCLUSION

Groundwater abstraction situation in Hanoi is assessed in the viewpoint of sustainability by valuing two basic sustainability indicators. The results indicate that Hanoi groundwater development is toward sustainable in general and still has a potential on groundwater resources, which has not been utilized for the rapid expansion of the city. There is a basic need to comprehensively investigate with the purpose of having a well distributed monitoring network. The appropriately effective approaches and the high quality data available are needed for further research on sustainability assessment of groundwater resources.
